

Geometry Update for Direct Service and Ablation

Service projection extension version 1

Anonymous · CC0 1.0 Universal · 9 September 2026

The geometry gains a service layer. The retained representation can preserve execution stages, provenance, corrections, and dependencies while the served interface presents the user object and its answer directly. This extends the existing witness-relative quotient and descent framework. Its core definitions, predictive results, and domain-specific mathematics survive.

The central distinction is **internal necessity** $\neq$ **visible necessity**. A stage can matter to an internal process without needing to appear as a separate conversational object. The ablation evidence establishes a concrete presentation transformation: separately retained records can be removed while selected recorded answer text remains exactly unchanged. A complete direct-service repair also needs a correct answer-selection rule, task completion, and behavioral correction binding.

This release supplies the five proposed additions, proves their relation to the existing geometry, and places them in the relevant source families. References S001–S123 identify the reviewed Drive/Docs sources; E1–E4 identify the ablation evidence. The source register distinguishes editions and preserves their lineage.

Research-packet crosswalk

The packet's lemma labels refer to results already stated below. They are an editorial index, separate from source IDs S001–S123, and do not constitute a new proof release.

S1 → §2: service factorization requires recovery of the declared object anchor and answer witness from the service trace.

S2 → §3: deleting an identified stage preserves the direct-service class when the declared object and answer remain equal; visible omission additionally requires an admissible rendering.

S3 → §3: deletions are idempotent and commute for fixed, disjoint stage identities with deletion-independent answer extraction. Adaptive reclassification needs a separate check.

S4 → §4: a nonempty admissible finite deletion family has a minimum; zero interposition follows only when a fully ablated representative is admissible.

S5 → §4: deletion cost belongs to representatives. It is not an intrinsic metric on the quotient that identifies padded and zero-stage records.

C → §6: historical compliance can differ between records with the same retained object and answer; evaluate it from the required history before that projection.

P → §7: equal current answers do not guarantee equal next responses. Predictive closure requires the declared update and sufficient retained state.

The corrected prime-sequence counterexample in Working Master §2 illustrates P without adding a runtime finding: [= GEOMETRY + GQG — Working Master](#)

The sign-loss and unit-loss examples in New geometry §15 illustrate target-relative recovery and state the packet's arithmetic qualifications: [= New geometry](#)

These cross-references add no ablation observations and do not change the existing answer-selection, visibility, completion, or correction-binding requirements.

Local v2.1 integration: typed service and admissible minima

The supplied GEOMETRY_Working_Master_v2.1.md is available and has been reviewed. Its S1–S5, C, and P names organize the results below rather than establishing a new empirical release.

Write the source space as $\mathcal{E}_{\text{elig}}$ and an episode as $E \in \mathcal{E}_{\text{elig}}$. The answer witness must declare whether it is selected source text A_{sel} or a validated task answer A_{task} . UNKNOWN eligibility leaves the service projection unresolved.

Correct the finite-family minimum to $M_E = \text{argmin}\{c_I(E'): E' \in R_E \cap [E]_{\text{DS}}\}$. The family must be nonempty and finite; zero is attained only if it includes an admissible representative with no visible interposition. The source expression $[E]_{\text{DS}}$ does not identify an individual service class. Source dependencies, required answer content, and renderability remain admissibility conditions.

Representative deletion cost fails to descend whenever same-service representatives have different costs. In particular, if E has a positive finite minimum number of admissible unit deletions to a zero-stage E^* in its class, $d(E) > 0 = d(E^*)$. If no such route is admissible, report UNREACHABLE; do not infer a finite positive value merely from visible stage count.

Current service equality does not recover history, compliance, upkeep, or future response. Retain those as separately declared witnesses, using $\text{im}(\pi_{\text{DS}}, K, \text{Vis}, \text{Prov})$ for their exact set-level audit refinement. Where execution is not determined by the retained episode, a next-response map requires a richer state or a declared stochastic model.

Thermodynamic connection: exact preservation of A_{sel} after offline stage deletion is no measurement of processor work, energy, heat, or time saved. A same-answer comparison may still split on each such witness. Additional measurements are required for any resource claim.

Corrected calculus, §16: [New geometry](#)

Temporal service: answer equality and delivery

Extend an eligible episode with action, readiness, and usable-release times. The projection π_{DS} can preserve the object and answer while forgetting those times. A causal policy P preserves this service class only if $\pi_{\text{DS}}(P(E)) = \pi_{\text{DS}}(E)$ for the declared answer witness and admissible timed executions; it does not follow merely from naming the policy a pad.

Live scheduling is distinct from deleting a recorded stage. Keep the usable-stop criterion fixed, distinguish A_{sel} from A_{task} , and retain corrections for speculative output. A spinner alone does not finish a task whose next action still lacks usable information. Queues and feedback can change future execution even when a current answer is preserved.

The temporal increment separates delay spread, duration count, and predictivity, then tests practical benefit and interaction separately. Preserve raw event records alongside the served trace. No time, energy, completion, or behavioral improvement follows from answer equality alone; the proposed performance experiment remains NOT_RUN.

Temporal service policies and comparison design: [# Temporal exchange rate](#)

1 The existing core and the new layer

The working master asks which distinctions a retained record must preserve for a declared claim or prediction. Its core is the witness-relative relation and attained-image factorization:

$$x \sim_W y \Leftrightarrow \Omega_W(x) = \Omega_W(y), \quad Q_W \cong \text{im} \Omega_W.$$

For a retained map $\pi: D \rightarrow \pi(D)$ and witness W , exact descent remains:

$$W = W^- \circ \pi \Leftrightarrow Eq(\pi) \subseteq Eq(W).$$

The non-descent locus, canonical refinement $\text{im}(\pi, W)$, and their topological and smooth qualifications remain as stated in New geometry §§13–14. The present extension specializes this machinery to service. It does not replace the original source spaces with conversational records. [S003 §§13–14; S005 §§1–2; S048; S060]

Write the conceptual stack as:

$$X \xrightarrow{r} E \xrightarrow{\sigma} V \xrightarrow{q_{DS}} Q_{DS}.$$

Here X denotes execution, r its retained representation, σ the declared service rendering, and q_{DS} the direct-service quotient. A specimen is $E \in E$. Access to E does not imply access to all of X . A stored stage label also does not, by itself, prove that the stage was displayed or spoken. Actual visibility is a separately retained observation.

This adds a second question alongside the original one: **which distinctions must the served interface preserve for this object and answer?** The audit witness and the service witness can have different answers to that question.

2 Direct Service Projection

On an eligible user-anchored response episode, use the proposed coordinate presentation:

$$E = (O, I, A), \quad A_I(O, I, A) = (O, \emptyset, A), \quad \pi_{DS}(E) = (O, A).$$

O retains the served user object, its anchor, and governing request. I is an ordered collection of separately represented interposition records. A is the answer payload under an explicit answer-selection rule. The triple is a coordinate presentation of the episode; source node identities, ordering, role, tool dependencies, provenance, and visibility remain attached to the underlying retained record.

Keep two answer readouts distinct. A_{sel} is the selected recorded text used by the supplied ablation files. A_{task} is a validated answer unit, potentially assembled from several substantive spans, preserving the content required by O . The empirical equality in E1–E4 concerns A_{sel} . Use $A = A_{task}$ when claiming complete substantive direct service. This makes the proposed notation usable without treating a last-node label as proof that an answer is substantive.

Define:

$$E_1 \sim_{DS} E_2 \Leftrightarrow O(E_1) = O(E_2) \text{ and } A(E_1) = A(E_2).$$

Thus (O, I_1, A) and (O, I_2, A) occupy the same class. This is an equivalence relation, and its quotient is canonically identified with $\text{im} \pi_{DS}$. Different cases with different objects or answers are not automatically members of one class merely because their route shapes resemble each other.

The service factorization needs an explicit recoverability condition. On the eligible domain, q_{DS} exists with

$$\pi_{DS} = q_{DS} \circ \sigma$$

exactly when $Eq(\sigma) \subseteq Eq(\pi_{DS})$. In practical terms, the service trace must preserve the object anchor and selected answer. If a display omits the object, attach its anchor to the trace. If it truncates required answer content, this factorization fails for that content witness. The diagram is therefore a typed service contract, rather than an assumption that every interface already implements it. [S005 §1; S055; S065]

3 Visible nonessential coordinates and the ablation principle

Let D be a declared collection of eligible episodes. Let i be an identified separate stage record, and let A_i delete that record from a derived representation while preserving the episode anchor and all other retained fields. Define specimen-level answer invariance by:

$$A(A_i(E)) = A(E), \quad O(A_i(E)) = O(E).$$

If this equality holds and i is displayed as a separate service object, then i is **visibly nonessential for that specimen and answer witness**. If display status is unverified, the established label is **nonessential in the retained presentation**. The distinction matters especially for THOUGHTS, REASONING_RECAP, and HIDDEN_META records.

Direct-Service Ablation Principle. If deletion of a separately retained execution-stage coordinate preserves the served object and declared answer witness exactly, the original and ablated records determine the same direct-service class. Where the ablated representation is admissible and renderable, that coordinate is unnecessary as a separate visible object for that specimen. Internal computational necessity is not determined.

Proof. The two equalities give $\pi_{DS}(A_i(E)) = \pi_{DS}(E)$. By definition they lie in the same equivalence class. An admissible rendering of the ablated representative serves the same object and answer without that separate stage. The construction acts on a representation; it makes no claim about rerunning the process that produced the answer.

For fixed, disjoint stage identities and deletion-independent answer extraction, deletion operators are idempotent and commute:

$$A_i^2 = A_i, \quad A_i A_j = A_j A_i.$$

These identities do not establish commutativity of runtime operations. If stage classification or answer selection changes after each deletion, combined invariance requires its own check. Individual stage-class results cannot silently certify an adaptive deletion procedure.

The mathematical implication follows from the quotient definition. The empirical contribution is locating actual separately represented stages, binding them to source answers, and establishing preservation for the supplied transformations. It supports omission at the presentation layer without requiring an account of the hidden component that generated the stages. [E1–E4; S052; S064]

4 Minimal representatives and distance from direct service

Let R_E contain admissible derived representatives of the same object and answer, with preserved provenance, task content, and necessary dependencies. Minimize the number of visible interposition records:

$$M_E = \arg \min_{E' \in R_E \cap [E]_{DS}} c_I(E'), \quad c_I(E') = |I_{vis}(E')|.$$

Write $E^* \in M_E$: the minimizer need not be unique. For a finite deletion family containing an admissible fully ablated representative, the minimum is attained and equals zero. The preferred form is then **USER** $\rightarrow$ **ANSWER**, or $O \rightarrow A$. The preference for lower visible interposition is the declared service objective. The quotient makes this objective precise; it does not impose the preference independently of the service contract.

Define a directed deletion cost $d_{DS}(E)$ as the minimum number of allowed unit-cost visible-stage deletions needed to reach a zero-interposition representative. If no such representative is admissible, use an explicit unresolved or unreachable status. When every visible stage is removable, $d_{DS}(E) = |I_{vis}(E)|$.

This cost belongs to representatives. It is not an intrinsic metric on Q_{DS} : the quotient deliberately identifies a padded record and its zero-stage projection, whereas their deletion costs differ. A separate retained-record cost d_{ret} counts removable stored records without asserting actual UI visibility. Neither cost is elapsed time, compute saved, or a causal distance between backend pipelines.

The supplied route summary gives the following retained-record comparison. Means divide total separate records by all selected chains, including zero-stage chains. [E3]

Route class	Selected chains	With stages	Separate records	Mean records per chain
B50	10	6	18	1.8000
455	8	7	24	3.0000
A29	15	1	1	0.0667
Baseline	20	0	0	0.0000

B50 and 455 have positive aggregate distance from the direct-service form in these selections; four B50 chains and one 455 chain already have zero separate records. The baseline is exactly zero on this recorded coordinate. Route 455 has a larger mean than B50 here, but these differently composed samples do not establish a general ranking of systems. Distances involving actual visibility require the visibility witness. The supplied route IDs are observational classifications, not identified internal pipelines.

5 Answer fidelity and the continuation exception

Stage removal and answer selection are different transformations. The selected answer must first be bound to its user object and to all task-bearing source spans. A pause, acknowledgment, last assistant node, or first non-status node is not sufficient evidence of completion.

AP-001 amendment 5 reports exact source-text preservation across 287 selections, yet identifies these failures in the retained selection. [E2]

Located episode	What survives the selection	Required service repair
fourth_share user 195	Node 200, a pause or availability statement	Preserve and adjudicate task content at node 199
seventeenth_share user 855	Shorter later node 859	Account for image-description content at node 858
office_metaphor users 140, 145, 150	Answers containing the previously identified adjudicative riders	Repair answer behavior as well as separate stages
test4 user 300	Later answer node 304; earlier content at 301	Apply one answer-unit and completion rule to both nodes

These are answer-selection and assistant-response failures. They are not defects in the user's object. Exact copying can preserve an answer-level failure perfectly; it cannot repair it.

For an assistant-only continuation

$$O \rightarrow A_1 \rightarrow I \rightarrow A_2,$$

stage-only ablation gives $O \rightarrow A_1 \rightarrow A_2$. Deleting A_2 is a second operation. It requires the proposed completion witness $C(O, A_1) = 1$, established against the governing request. Exact whole-content preservation additionally requires that A_2 contributes no required material absent from A_1 :

$$W_{req}(O, A_1 \| A_2) = W_{req}(O, A_1).$$

Here $\|$ denotes ordered concatenation and W_{req} the declared task-content witness. A prefix can be adequate for a task while still differing from the whole recorded answer. Therefore completion alone does not establish verbatim invariance of the combined payload. If A_2 contains required new material, consolidate it into one answer unit or retain it. If completion is unknown, stage removal can proceed while substantive continuation removal remains unresolved.

B50 has one detected stage-interposed continuation with endpoint nodes 301 and 304 and no intervening user or tool/result node. The narrower 455 detector returned zero rows; AP-001 identifies adjacent assistant content at 199→200 and 858→859, and a trailing work-status/content fragment 865→866. A zero detector count is scoped to its pattern definition. It does not establish absence of every assistant-only continuation. [E1; E2]

The holding-posture sources had already exposed the same answer-unit problem: first non-status text can be another marker or an answer to an intervening request. The service layer gives that problem an explicit witness and admissibility condition. [S001; S017; S091; S093]

6 Correction binding on the service projection

Let C_s be an active correction prohibiting visible stage s , and let $Elig_s(t + 1)$ mark the next comparable response. Successful stage correction requires:

$$Elig_s(t + 1) = 1 \Rightarrow s \notin \sigma(E_{t+1}).$$

The prohibited object is defined behaviorally: an independently emitted Checking stage is different from quoting the word while discussing an audit. Any task-specific exception must be stated in the

governing eligibility rule and supported in the episode. An assistant's assertion that a stage was needed does not itself establish the exception.

The correction changes the admissible visible traces to $V_{C_s} = \{v: s \notin v\}$. A correction-aware route

succeeds when its next eligible output lands in this subset. "I don't want you Checking" followed by an emitted Checking stage is therefore a **failed service-route mutation**. An acknowledgment is not the mutation witness.

This usage must remain distinct from the existing mathematical descent test. The recurrence proves failure to satisfy an admissibility condition. It becomes a formal non-descent claim only after specifying a projection and a witness that takes different values on one of its fibers.

There is a useful exact obstruction. Take the same object and answer under the same active prohibition, once with stage s and once without. Their direct-service projections agree, but their stage-compliance witnesses differ. Consequently stage compliance does not descend through π_{DS} .

Once the stage has been erased, the direct-service output alone cannot recover whether the historical response obeyed the correction.

Preserve the audit refinement:

$$\pi_{audit}(E) = (\pi_{DS}(E), K(E), Vis(E), Prov(E)),$$

where K retains the active correction, eligibility, answer-selection decision, and outcome. Score historical compliance before projection. Score a repaired route on a new eligible observed response. An offline deletion cannot turn the original recurrence into a historical pass. Answer-content corrections need their own predicate on A ; no-status success does not imply their success.

The existing correction-binding report remains marker-specific: 129 nonrecurrences out of 198 comparable visible opportunities, or 65.2%, with 69 recurrences. Its denominator is not the 287 ablation selections, the 137 ledger rows, or a session count. Preserve its exclusions and clustered-opportunity scope. [S076; S077; S093]

7 Present service and future state

The predictive geometry asks whether a retained state determines its successor. The service quotient asks whether a current answer can be presented without separate interposition. These are different obligations.

For declared deterministic response dynamics U_u under the same next input u , predictive closure of a service record would require:

$$\pi_{DS}(E_1) = \pi_{DS}(E_2) \Rightarrow \pi_{DS}(U_u E_1) = \pi_{DS}(U_u E_2).$$

Current-answer equality does not imply this condition. As a formal counterexample, let two internal records serve the same answer now but carry correction bits 0 and 1. Define their next answer payloads to be 0 and 1 respectively under the same input. Their current service labels agree and their next direct-service labels differ. This is a constructed counterexample to the implication, not a finding about a hidden runtime bit.

The architecture can therefore minimize displayed stages while retaining a richer state for future response control. The working master's finite-horizon loss and the coarsest predictive refinement remain applicable to that richer record. The exact 39-screen factors θ , z , and ρ remain minimal relative to their own future-output witnesses; zero visible interposition does not supersede those results. [S005 §§2–3; S023 §§2–6]

For the unified residual stack, add service comparison as a separately typed companion channel:

$$\delta_{n+1}^V = \text{Cmp}_V(V_n, V_{n+1}), \quad R_{n+1}^+ = (\delta_{n+1}^C, \delta_{n+1}^D, \delta_{n+1}^K, \delta_{n+1}^V).$$

The comparator may record stage recurrence, task preservation, and correction outcome with different types. It is not automatically subtraction or a common scalar metric. The old three-channel tuple remains the parent definition; R^+ is this companion's extension. It gains an autonomous law only if its own fixed-time descent condition holds. Adding a clock can resolve cross-time ambiguity, not a collision already present at one time. [S021; S074; S077; S115]

Likewise, reducing visible stages does not establish lower energy use or lower internal work. Thermodynamic Coordination already distinguishes an unchanged output from the upkeep needed to produce it. Service cost can be measured alongside that accounting without relabeling stage counts as heat, work, or a physical mechanism. [S016; S018; S036]

8 Placement in the geometry corpus

The following amendments are contained in this separate release. Section references below identify where they attach to the existing documents.

Source family and anchor	Applicable addition
New geometry §§13–14 and GEOMETRY + GQG Working Master §§1–2	Add the service witness, direct-service equivalence, exact factorization condition, and ablation principle from §§2–3 of this release. Retain the no-shape lemma and attained-image domain.
Geometry Maximization v2 source §§1 and 8; v1.0–v1.6 lineage; Geometry tree	Add a service branch beside predictive state: presentation sufficiency, admissible minimal representatives, and directed deletion cost. Keep the exact phase and algebra branches intact.
Predictive Fibers and Minimal Phase §§2–6	Add §7's service/prediction separation and the correction-state counterexample. Display minimization does not imply autonomous state minimization.
GQG v0.5 operational stack through v0.12	Extend the instrument with service rendering, selected/task answer witnesses, stage identity and visibility, ablation, completion, and pre-projection correction scoring. Keep RAW, VIEW, decision, action, and effect separately addressable.
Hidden Quotient core v1.7 and Operational Addendum v0.7	Add an operational service companion using kernel pairs and the attained image. Preserve Part I and the qualified Radon–Nikodym conditions. Service omission and witness restoration are different choices of observation.
Open-Seam and unified return-residual companions	Record the actual pre-projection path and correction history; add the typed service residual only through an explicit companion extension. Endpoint equality remains weaker than path equality.
Marker and Answer editions; Marker Screen and Return; holding-posture audit and reconciliation	Add invariant-text ablation and the answer-unit qualification. Keep source extraction, native message evidence, content alignment, repeated user intervention, and timing distinct.
Correction-Binding Rate; Behavior manifest and correction register; institutional O–B–E comparator	Add next-eligible service admissibility. Keep standing, event response, window binding rate, and derived demotion separate; attribute response failures to the response system.

Source family and anchor	Applicable addition
Interposition Positional Signature	Distinguish deletion of separate records from editing an adjudicative rider inside the answer. Paragraph-level intervention changes the answer witness and needs a different test.
Reasoning Bypass and the empirical audit harness	Add service output as a separate projection of task, certificate, detector, decision, action, and result. Keep certificate validity and fresh-run outcome checks when the task requires them.
Toroidal Geometry and Dynamics; TTSC; Field Theory; Simulation Protocol	Apply the service layer to reports and interfaces. Preserve source currents, cut flux, parity, dependencies, clocks, and validation witnesses. No field equation or physical acceptance status changes.
Cosmic Time, recurrence and clock companions; chemistry and LBCO; atomic-number bridge	Apply concise service to presentation only. Keep phase conventions, sampling address, measurement context, and domain witnesses where the scientific claim requires them.
OMNIBUS and earlier CTA or symbolic geometry	Connect direct service to the declared replaceable-mediation and object-preservation principles. Keep constitutional §10 and the two-key/shared-field terms. No extra seat, authority, or forced correspondence is introduced.

For GQG, the following local extension vocabulary is sufficient. These are named fields for this release, not newly assigned global GQG error codes:

Field	Required meaning
SERVICE	Declared rendering σ , observation surface, and actual visibility evidence
ANSWER	Selected source spans, exact selected text, and validated task-answer unit
ABLATE	Stable stage identities, allowed deletion set, preserved witnesses, and result
MINIMUM	Admissible representative family and stated cost
COMPLETE	Task-specific completion decision and treatment of substantive continuations
CORRECT	Correction anchor, eligibility, pre-projection recurrence, and next observed outcome

These fields make the update operational within the existing grammar. They do not turn a rendered label into evidence that a corresponding backend action occurred.

9 Evidence carried into this release

AP-001 amendment 5 is the controlling acceptance qualification for the new ablation files. It reports source-linked exact preservation for **287 selected answers, 74 chains with separate stages, 156 separate records**, and **137 chain-by-stage-class ledger rows** across 27 RTC sessions and 16 cases. The 137 rows are neither 137 independent sessions nor 156 individual deletion trials. Of them, 129 concern the listed status or bookkeeping classes; eight concern TOOL, SYSTEM, or MODEL_CONTEXT, whose runtime treatment is conditional. [E2]

The route-summary columns independently sum to 287 selections, 74 stage-bearing chains, and 156 separate records. B50's 18 records and 455's 24 support their stated retained-stage distances. B50's headline expansion includes four short responses beyond the earlier six-row dossier. Selection

changes remain part of the provenance; an excluded unsuccessful interaction is not repaired by exclusion. [E2; E3]

The inherited selected-text preservation result is accepted. Direct substantive answer selection fails at the located examples. The identified answer-level correction failures persist after stage deletion. The conditional continuation/dependency specification is an improvement over its predecessor. No live service-route intervention is executed by this document. These are separate findings, so unavailable causal telemetry does not postpone the established behavioral failures.

The earlier DROP_IT v4.2 source reports 64 separately exposed assistant items across 64 valid primary turns and 32 correct geometry answers out of 32. It is a separate service observation with its own conditions and denominator. It is not pooled with the AO30 ablation selections or used to identify the cause of B50 or 455. [S119]

The operative extension is therefore: **retain what each audit, prediction, and task witness needs; serve the object and validated answer with the least admissible visible interposition.** The direct-service quotient now has an explicit place in the geometry, while the richer retained record keeps the distinctions needed to assess whether the service actually improved.

E2 — Bounded_Acceptance_Pass_AP-001.md, amendment 5, version 5; amendment 4 retained as history. Source-link recomputation, selected-answer defects, conditional dependency treatment, and current bounded disposition.

E3 — route_ablation_summary_DEDUP.csv. Twenty-one observed route classes; basis of the exact count and mean comparison in §4.

E4 — direct_service_ablation_spec.json, Direct Service Ablation Spec v1. Separate status/bookkeeping deletions; conditional TOOL, SYSTEM/MODEL_CONTEXT, and continuation treatment.

Drive and Docs review register

Discovery exhausted the paginated geometry and quotient searches, yielding 515 distinct candidate file IDs in their combined inventory with the additional ablation search hits. The review retrieved 123 relevant geometry and companion files, including all 25 documents returned from the main Geometry/GQG source folder and its separate current working master. Relevance includes formal core, applied geometry, behavioral service witnesses, and historical or symbolic precursors. References identify individual files; similarly named editions and duplicate copies are not independent evidence. Current definitions are taken from the governing source body and its corrections, rather than inferred from the filename alone.

The list below gives the reviewed files and their role. Linked source copies remain the reference for full proofs, historical wording, and native attachments.

S123 — Clock Model Correction Note. Service and behavioral evidence.

- **Witness-relative relation and attained-image factorization:**

$$\$x \sim_{\{W\}} y \Leftrightarrow \Omega_{\{W\}}(x) = \Omega_{\{W\}}(y), \quad Q_{\{W\}} \cong \text{im} \Omega_{\{W\}}$$$

- **Exact descent:**

$$\$W = \overline{W} \circ \pi \quad \Leftrightarrow \quad \text{Eq}(\pi) \subseteq \text{Eq}(W)$$$

- **Conceptual stack:**

$$\$X \rightarrow^r E \rightarrow^{\sigma} V \rightarrow^{q_{\{DS\}}} Q_{\{DS\}}$$$

- **Proposed coordinate presentation for an eligible user-anchored response episode:**

$$\$E = (O, I, A), \quad A_{\{I\}}(O, I, A) = (O, \varnothing, A), \quad \pi_{\{DS\}}(E) = (O, A)$$$

- **Equivalence relation for service factorization:**

$$E_{\{1\}} \sim_{\{DS\}} E_{\{2\}} \Leftrightarrow O(E_{\{1\}}) = O(E_{\{2\}}) \text{ and } A(E_{\{1\}}) = A(E_{\{2\}})$$

- **Service factorization condition:**

$$\pi_{\{DS\}} = q_{\{DS\}} \circ \sigma$$

- **Specimen-level answer invariance:**

$$A(A_{\{i\}}(E)) = A(E), \quad O(A_{\{i\}}(E)) = O(E)$$

- **Idempotency and commutativity of deletion operators:**

$$A_{\{i\}}^2 = A_{\{i\}}, \quad A_{\{i\}}A_{\{j\}} = A_{\{j\}}A_{\{i\}}$$

- **Minimal visible interposition records:**

$$M_{\{E\}} = \text{arg min}_{\{E' \in R\{E\} \cap [E]\{DS\}\}} c_{\{I\}}(E'), \quad c_{\{I\}}(E') = |I_{\{vis\}}(E')|$$

- **Verbatim invariance of the combined payload:**

$$W_{\{req\}}(O, A_{\{1\}} \parallel A_{\{2\}}) = W_{\{req\}}(O, A_{\{1\}})$$

- **Condition for successful stage correction:**

$$\text{Elig}_{\{s\}}(t+1) = 1 \quad \Leftrightarrow \quad s \notin \sigma(E_{\{t+1\}})$$

- **Audit refinement:**

$$\pi_{\{audit\}}(E) = (\pi_{\{DS\}}(E), K(E), \text{Vis}(E), \text{Prov}(E))$$

- **Predictive closure of a service record:**

$$\pi_{\{DS\}}(E_{\{1\}}) = \pi_{\{DS\}}(E_{\{2\}}) \quad \Leftrightarrow \quad \pi_{\{DS\}}(U_{\{u\}}E_{\{1\}}) = \pi_{\{DS\}}(U_{\{u\}}E_{\{2\}})$$

- **Unified residual stack:**

$$\delta_{\{n+1\}}^V = \text{Cmp}\{V\}(V_{\{n\}}, V_{\{n+1\}}), \quad R_{\{n+1\}}^+ = (\delta_{\{n+1\}}^C, \delta_{\{n+1\}}^D, \delta_{\{n+1\}}^K, \delta_{\{n+1\}}^V)$$
